

Information in practice

Effects of a web based decision aid on parental attitudes to MMR vaccination: a before and after study

Cate Wallace, Julie Leask, Lyndal J Trevena

Abstract

Objective To determine whether an evidence based decision aid on the measles, mumps, and rubella (MMR) vaccine changed parents' attitudes towards vaccination.

Design Before and after study.

Setting Website promoted through search engines and online parenting and health websites.

Participants 158 people completing online questions out of 1277 who accessed the website.

Intervention Evidence based decision aid with text and graphical representation of the possible outcomes of measles, mumps, and rubella diseases compared with MMR vaccination.

Main outcome measures Attitudes towards MMR vaccination.

Results Significantly more participants indicated they were "leaning towards" vaccination after using the decision aid (39% before *v* 55% after, $P < 0.001$). Compared with those who were undecided or "leaning away from" vaccination after using the decision aid, participants "leaning towards" it were more likely to strongly value its potential to protect their children from the serious side effects of disease (98% *v* 84%) and other children who could not be vaccinated for medical reasons (68% *v* 25%). Participants with an unfavourable attitude to vaccination were more likely to be very concerned about the rare side effects of vaccination (78% *v* 57%), have residual concerns about autism and bowel disease (78% *v* 27%), and anticipate guilt should their child have an adverse reaction (77% *v* 50%). Those with a positive attitude to vaccination after using the decision aid were also more likely to feel well informed (83% *v* 48%).

Conclusions A web based decision aid significantly improved parental attitudes to MMR vaccination. Residual concerns about autism and bowel disease and the rare chance of serious complications remained as attitudinal barriers to some parents.

Introduction

The controversy over the alleged association between autism and the combined measles, mumps, and rubella vaccine (MMR) has led to declining coverage and resultant disease outbreaks in the United Kingdom and Ireland.^{1 2} In countries such as Canada, the United States, New Zealand, and Australia many parents have also expressed concern over the safety of the vaccine, which, as shown by the UK experience, may rapidly threaten immunisation targets and disease control should this concern translate into behaviour.

There have been concerted efforts to address parental concerns about the MMR vaccine, with brochures, fact sheets, and websites designed to inform parents of the facts. Yet there is only limited evidence that providing didactic information has

alleviated parents' concerns and changed their attitudes towards the vaccine. Despite the abundance of information, parents have reported they believe the information they have received is inadequate, biased, or inaccurate and have routinely requested more detailed information about the risks and benefits of the vaccine.³⁻⁶

This apparent contradiction between the available information and parents' perception of its veracity may indicate a need to change communication strategies—rather than viewing parents as "blank slates" on which information is imprinted, we should acknowledge the critical and social context in which they interpret messages.⁷ An effective public health response must be relevant and responsive to parental values and preferences, engage with parents as decision makers, and endeavour to transform their views collaboratively as opposed to dictating their choices coercively.⁸

Decision aids may serve this purpose. They are designed to help people understand their options and potential outcomes, to consider the possible benefits and harms of their choices, and to increase consumer participation in decision making.⁹ They typically include probabilistic information in numerical and graphical format, information about the potential outcomes of each choice, and exercises to clarify values. Decision aids have been shown to reduce decisional conflict, improve knowledge, and change behaviours.⁹ However, few studies have applied them to immunisation,¹⁰ and no studies of decision aids for MMR vaccination have been published.

We report on a pilot study of an interactive, web based decision aid for parents questioning MMR vaccination. Our aim was to assess the feasibility of a larger randomised trial of effectiveness of the decision aid. Our primary interest was whether the decision aid could improve attitudes to MMR immunisation. The internet provides a previously unexplored environment for assessing the effect of a decision aid about MMR vaccination. Firstly, it may capture those who do not usually approach their healthcare provider until the immunisation decision has been made. Secondly, parents navigating cyberspace routinely encounter competing, and often controversial and highly emotive, information on which to base their decisions.^{11 12} Finally, the online format allows the aid to be interactive, which also allows for the expedient collection of data from respondents.

Methods

Decision aid development

We developed the pilot MMR decision aid in the first two months of 2004. It was designed to comply, as much as possible, with the CREDIBLE criteria as defined by the Cochrane Review of Deci-

Fig 1 Screen from MMR vaccination decision aid: direction of leaning about vaccination

sion Aids.^{9 13} The aid provided numerical and graphical evidence of the risks associated with the diseases, alongside the potential risks associated with the vaccine, and provided references for these estimates. We used Australian data where possible, supplemented with evidence from large international epidemiological studies, systematic reviews, and meta-analyses.

Frequently asked questions were addressed, including information about the alleged association between autism and MMR vaccination. The aid listed some key advantages and disadvantages of MMR vaccination, and users were asked to rate the importance of these on a three point scale (“Very important to me,” “Slightly important to me,” and “Not important to me”). Users were also asked to rate their attitudes to MMR vaccination, both before using the decision aid and again afterwards, on a three point scale (“Leaning away from MMR vaccination,” “Undecided,” and “Leaning towards MMR vaccination”). After using the decision aid, users’ information requirements for decision making were assessed with four questions (see table 2) on a three point scale (“Yes,” “Unsure,” and “No”).

The aid was written for a reading age of 12 years. We consulted a range of stakeholders about its content, design, and layout, including immunisation and decision aid experts, health professionals, and parents. The aid was located via the website of the Australian National Centre for Immunisation Research and Surveillance (NCIRS) at www.ncirs.usyd.edu.au/decisionaid (figs 1 and 2 show two sample screens from the aid).

Recruitment

After ethical approval of our study, the decision aid was advertised on a popular parenting website and a small number of government and parent-friendly websites, mainly in Australia and New Zealand. The decision aid went live on 20 April 2004, and data collection closed on 31 January 2005.

Study design and outcomes

Respondents had open access to the decision aid, which was designed for sequential movement through its 21 screens but with the option to move to any section via a menu. Respondents completed online questions in a stepwise fashion using radio buttons and free text but could proceed without completing questions if they chose. At the end of the aid, respondents were asked to complete demographic details. Using a before and after design, the primary outcome was change in attitude towards the MMR vaccine.

Data analysis

Respondents’ attitudes were coded as -1 for “leaning away from,” 0 for “undecided,” and 1 for “leaning towards” vaccination. We

How to compare the risks

What are the potential risks of Measles compared with the potential risks of MMR?

What are the potential risks in a group of 100 children and adolescents who get measles?	What are the potential risks in a group of 100 children who have the MMR vaccination?
8 may get diarrhoea ⁹	10 may experience local inflammation at the injection site, discomfort or fever ⁹
7 may get an ear infection ⁹	5 may develop swollen glands or joint pain ⁹
6 may get pneumonia ⁹	3 may develop a non-infectious faint red rash ⁹
1 may be hospitalised ⁹	1 may develop swelling of the salivary glands ⁹
The remaining 93 children may experience symptoms such as fever, rash, runny nose, loss of appetite, and red and painful eyes ⁹	83 may not have any side-effects
333 out of 1 million children reported to have measles may die as a result. ⁹	33 out of 1 million children may develop a temporary tendency for bruising or bleeding (thrombocytopenia). ¹⁰
5000 out of 1 million children may experience a fever induced convulsion. ⁹	1000 out of 1 million children may experience a fever induced convulsion. ⁷

Fig 2 Screen from MMR vaccination decision aid: comparison of risks

calculated respondents’ mean score before and after they viewed the aid. We used Wilcoxon’s matched pairs signed ranking test (by means of SPSS version 11.5) to determine whether the change in these scores was significant. We cross tabulated each respondent’s “leaning” before using the aid against their “leaning” after using the aid. This allowed identification of the number of people who were less favourably or more favourably disposed to the MMR vaccine after using the aid, and the number whose opinion was unaltered.

We dichotomised respondents’ perceived importance of the advantages and disadvantages of MMR vaccination as “very important” or other (“slightly important” and “not important” combined). We compared ratings for each advantage and disadvantage with respect to whether respondents were leaning towards MMR vaccination or staying undecided or leaning away from vaccination after viewing the decision aid. We also measured the extent to which people with favourable and unfavourable attitudes to MMR vaccine perceived that their information needs had been met.

Results

Respondents’ characteristics

A total of 1277 people accessed the site, with 158 completing the aid by providing responses to set questions. Of these 158 respondents, 62 (39%) supplied demographic information: 55 were parents, 52 with children aged less than 5 years; 53 were aged between 25 and 44 years; and 39 had a university degree. In addition, 42 were from Australia, with the remainder from New Zealand, then the US, UK, Canada, Europe, and Asia. Thirty nine respondents were prepared to be contacted for follow-up by email or telephone.

Attitudes to MMR before and after decision aid

Table 1 shows changes in the 158 respondents’ leanings before and after using the decision aid: 48 shifted in a positive direction towards MMR vaccination, and the proportion of respondents “leaning towards” MMR vaccination increased significantly from

Table 1 Changes in attitudes to MMR vaccination among 158 respondents after use of a web based MMR decision aid. Values are numbers of respondents

Attitudes to vaccination before using decision aid	Attitudes to vaccination after using decision aid*

§Participants less favourably disposed to MMR vaccination after using the decision aid (n=12).

61 (39%) before using the aid to 87 (55%) afterwards (P<0.0001).

Beliefs about MMR vaccination

Table 2 shows respondents’ views of a list of advantages and disadvantages of MMR vaccination according to whether they reported a positive attitude towards vaccination or a negative or undecided attitude. As might be expected, participants with a positive attitude towards MMR vaccination were more likely to perceive all of the listed advantages of MMR as important to them than those who remained undecided or were “leaning away from” vaccination. They were also less likely to perceive rare but serious side effects of vaccination as being important and were less likely to have residual concerns about autism and bowel disease.

The most important perceived advantage of MMR vaccination among those with a positive attitude was protection against the serious symptoms of measles, mumps, and rubella (98% rated this as “very important,” compared with 84% of those with a negative or undecided attitude). Other advantages that most respondents with a positive attitude considered very important were the protection of other children who could not be vaccinated for medical reasons (68%, versus 25% of those with negative or undecided attitudes) and protection against common symptoms of measles, mumps, and rubella (63%, v 30%).

Participants who remained “undecided” or “leaning away from” vaccination after using the aid were more likely to consider the disadvantages of MMR vaccination as very important, particularly the chance of rare but serious complications (78%, v 57% of those “leaning towards” vaccination), residual concerns about autism and bowel disease (78%, v 27%), and fear of feeling guilty or responsible should their child have an adverse reaction to the vaccine (77%, v 50%). Other reasons that respondents cited in the free text box for not getting their child vaccinated included concern over mercury in vaccines, interest in alternative types of disease prevention, family experience of serious complications (including autism and inflammatory bowel disorders), and previous adverse reactions.

Among all respondents, perceived disadvantages of MMR vaccination included the unproved link between MMR vaccination, bowel disease, and autism (50% considered it “very important”) and the potential for feelings of guilt or responsibility if harm occurs as a result of MMR vaccination (62% “very important”).

Information needs for decision making

Respondents who were “leaning towards” MMR vaccination after using the decision aid were more likely to feel that they knew their options and that they had enough information to make a

Table 2 Beliefs of 158 respondents about MMR vaccination by their attitudes to vaccination after use of a web based MMR decision aid. Values are numbers (percentages) of respondents rating advantages or disadvantages as “Very important” or answering “Yes” to questions about information needs for decision making

Pros and cons of vaccination and information needs	Attitude to MMR vaccination	
	“Leaning towards” (n=87)	“Undecided” or “Leaning away from” (n=71)
Advantages of MMR vaccination		
My child will be better protected from common symptoms of diseases such as rash, high fever, red and painful eyes, swollen glands, and joint pain	52/83 (63)	19/63 (30)
My child will be better protected from the potentially serious complications of these diseases (such as encephalitis or death)	81/83 (98)	53/63 (84)
I will not have to take time off work to care for my child if he or she gets one or more of these diseases	11/83 (13)	4/63 (6)
My child won’t face the restrictions imposed by some schools and childcare centres that exclude children who have not been vaccinated	33/83 (40)	9/63 (14)
My vaccinated child is less likely to pass on diseases to the small number of children who are unable to be vaccinated for medical reasons	56/82 (68)	16/63 (25)
Disadvantages of MMR vaccination		
My child may have some localised swelling where he or she received the injection, have a non-infectious rash, mild cold and flu-like symptoms, or a fever 5-12 days after the vaccination	6/75 (8)	13/63 (21)
My child may be the 1 in a million children who experiences a serious complication such as a severe allergic reaction or encephalitis	43/75 (57)	49/63 (78)
If my child experiences a severe complication I may feel guilty or responsible for getting him or her vaccinated	37/74 (50)	47/61 (77)
Even though the association between MMR and bowel disease and autism has been disproved, I might feel some concern about these diseases and vaccination	20/75 (27)	49/63 (78)
If I choose to vaccinate my child I may be socially ostracised by friends, family, or members of my cultural or religious group who do not agree with vaccination	2/75 (3)	5/62 (8)
Information needs for decision making		
Do you know what options are available to you?	74/81 (91)	51/65 (78)
Do you know which advantages of MMR vaccination are most important to you?	81/81 (100)	59/64 (92)
Do you know which disadvantages of MMR vaccination are most important to you?	80/81 (99)	62/65 (95)
Do you feel that you have enough information to make decision about whether to vaccinate your child with MMR?	67/81 (83)	32/66 (48)

Denominators vary because respondents did not answer all the questions.

decision (table 2). Of those who remained undecided or were leaning away from vaccination, most (78%) said that they knew their options, but 52% still felt that they didn’t have enough information to make a decision or remained unsure. Among all respondents, 32/147 (22%) remained negative toward vaccination despite feeling well informed.

Discussion

This pilot study shows that an evidence based decision aid significantly improved parental attitudes towards MMR vaccination. It also shows that those respondents who remained undecided or negative towards vaccination after using the aid were more likely to have concerns about adverse reactions to the vaccine and residual concerns about autism and bowel disease despite a balanced presentation of the evidence. Valuing protection against the common symptoms of measles, mumps, and rubella and feeling well informed were factors in having positive beliefs about MMR vaccination.

Internet based recruitment makes it difficult to estimate how representative our respondents were of the general population

of those questioning MMR. However, 61% of those stating their initial preferences were either “leaning away from” or “undecided about” MMR vaccination, indicating that the aid was successful in attracting the target audience. The large number of respondents from other countries where the site was not promoted indicates the potential for interactive decision aids to have a public health impact beyond the intended local audience. The high hit rate for the aid indicates strong interest and activity on the internet.

The findings indicate that many users of our decision aid had attitudes inconsistent with the best available evidence. Even after completing the decision aid, 50% of respondents cited the (unsupported) association with autism as “very important” to them in deciding about MMR vaccination. In addition, 62% reported the potential for feelings of guilt or responsibility if harm occurs as a very important disadvantage of MMR vaccination. This supports previous findings that parental decisions about childhood immunisation can be more strongly influenced by perceived responsibility and anticipatory regret than by a numerical assessment of the risks and benefits of immunisation.^{14 15} It also supports findings that parents withhold vaccinations because a risk from a known disease may be more acceptable than a smaller risk of ambiguous or unknown consequences.¹⁶

Limitations of study

Because of the nature of the internet and the decision aid itself, users were able to access all parts of the aid without completing each section and were not compelled to provide their demographic details. Some users may have felt uncomfortable leaving such information on the website because of concerns over confidentiality. As a result, there is potential for selection bias from the low response rate. This may also have been due to the length of the aid, reflecting the difficulty of providing sufficiently comprehensive information to cover the main risks and benefits of MMR vaccine without being onerous to complete.

In addition, only 52 (84% of those providing demographic information) of the respondents reported having children of vaccination age: the other respondents' beliefs about vaccination may not be relevant and limit the generalisability of our results. Despite the problems of representativeness, online data collection represents a low cost and low maintenance way to obtain evaluative data and has promise if loss to follow-up can be minimised.

Future work

Further research is needed to clarify the effectiveness of the decision aid. Firstly, the aid could be adapted to be more interactive (such as response-dependent summary paragraphs) and to provide more in depth scientific evidence (including access to papers from medical journals, critiques of articles, and meta-analyses) that may be layered according to parents' information needs. Then, a randomised controlled trial of the online decision aid might allow the above methodological limitations to be addressed. Given the difficulty some parents have deciding whether to immunise their children with the MMR vaccine, such a study could examine changes in knowledge, decisional conflict, and anxiety. Of interest to government and immunisation advocates would be whether the aid improved the timeliness and completion of MMR vaccination among children of parents who are concerned about the safety of the vaccine.

Contributors: JL, LJ, Peter McIntyre, and Phyllis Butow designed the study. CW and LJ developed the decision aid. Linda MacDougall, Nikki Turner,

What is already known on this topic

Some parents have strong concerns over an unsupported link between MMR vaccine and autism

Interventions to address parental concerns are largely didactic, and few studies have examined their effectiveness

What this study adds

An online interactive decision aid improved parents' attitudes to MMR vaccination

Decision aids have the potential for wider application in providing advice about immunisation

and Helen Petousis-Harris provided advice on MMR decision aids. Crina Belvi, Brynley Hull, and the Centre for Innovation in Professional Health Education (CIPHE) assisted in online development and database setup. JL and LJ planned the analysis. LJ and CW analysed the data. Judy Simpson provided statistical advice. CW, JL, and LJ wrote the paper, and JL is the guarantor for the study.
